# 42. DIATOM UNITS AND THE PALEOGEOGRAPHY OF THE BLACK SEA IN THE LATE CENOZOIC (DSDP, LEG 42B)

Anastasia P. Jousé and Valentina V. Mukhina, Institute of Oceanology, Academy of Sciences of the USSR, Moscow

# INTRODUCTION

A major reason for the studying of the remains of diatom algae in the sediments of the Black Sea is to assist in determining the age and origin of the sediments, and in reconstructing the paleogeographical environments of sedimentation.

Until recently little was known about the deep-sea sediments of the Black Sea. The most valuable data were those relating to the diatoms in the Holocene sediments sampled during the expedition aboard *Akademik Vavilov* in 1971. These data show that the ecological diatom assemblages have undergone a succession of complicated changes after the Novoeuxian times, the last fresh-water stage of the history of the Black Sea.

The materials from *Glomar Challenger* have opened a new page in the history of the Black Sea, disclosing some hitherto unknown aspects in the development of the Black Sea diatom flora during the Pliocene-Pleistocene. Diatom remains in these sediments are one of the major organogenic components. There is extensive literature on the diatoms of Neogene age found in numerous sections of the Black Sea coasts, but the lack of comparable data off-shore has made the interpretation of the *Glomar Challenger* materials quite difficult.

### LOCALITIES AND PREPARATION OF SAMPLES

Geographical positions of the drilling sites of Leg 42B of the Deep Sea Drilling Project and of the *Akademik Vavilov* core are shown in Table 1 and Figure 1.

TABLE 1 Location of Drilled Sites in the Black Sea

Hole 379A	43°00.98'N	36°00.68'E	water depth 2171 m
Hole 380	42°05.98'N	29°36.90'E	water depth 2115 m
Hole 380A	42°05.99'N	29°36.82'E	water depth 2115 m
Site 381	41°40.25'N	29°24.96'E	water depth 1750.5 m
Core 1857	43°40'N	30°23'E	water depth 920 m

The material was treated in accordance with standard procedures used in the Laboratory of Micropaleontology, Department of Ocean Geology, Institute of Oceanology, Academy of Sciences, USSR. The method is as follows: 0.5 g of sediment is heated in a 10% Na<sub>5</sub>P<sub>3</sub>O<sub>10</sub> solution, then boiled for 60 minutes in a 30% H<sub>2</sub>O<sub>2</sub> solution. During the next 5 to 6 days, samples are washed in distilled water to remove tripolyphosphate and particles of pelite. Finally, the sample is washed and a portion of the material is mounted under a cover glass and examined under the microscope. This procedure allows calculation of the number of diatom valves per gram of sediment. The absolute abundance of diatoms is thus somewhat understated.

Figures 2 through 6 list the most characteristic diatom species from Holes 379A, 380, 380A, Site 380, and Core 1857, with their relative abundance in each examined sample.

Plates 1-23 show the photomicrographs of the most typical diatom species of the Pliocene-Pleistocene-Holocene of the Black Sea.

# Hole 379A

A total of 190 samples from 63 cores were examined; they include Samples 68, CC to Core 31, Samples 29-6, 2-4 cm, 29-5, 146-147 cm, 28-6, 121-123 cm, 26-4, 74-76 cm, 25-5, 95-106 cm, 23, CC to 22-4, 72-74 cm, 19-6, 56-58 cm, 19-2, 70-90 cm, 15-4, 52-70 cm, 15-4, 48-50 cm, and 14, CC to 13-3, 70-72 cm. Above Core 13 the sediments were barren of diatom remains, except for some sporadic (probably accidental) benthic diatom valves (Proshkina-Lavrenko, 1963).

The more abundant diatom-bearing sediments in Samples 25-1, 8-9 cm, 24-6, 49-51 cm, 24-6, 21-23 cm, and 8-2, 10-12 cm, contained a maximum of up to 167,000,000 valves/g and an average of 33,000,000 valves/g. Layers with less abundance contained from 5,000,000 to 14,000,000 valves/g, and those with the least content had no more than 5,000,000 valves/g. The sediments with a diatom content in excess of 33,000,000 valves/g are to be classed as diatom oozes. The diatom distribution throughout the section of Hole 379A is shown in Figure 2. Marine, brackish-water and freshwater halophiles are recognized, but all the marine species are euryhaline forms living in waters of low salinity. Most of the fresh-water diatoms are halophile species capable of withstanding a slight degree of salinity. Warm-water and relatively cold-water species are present.

The following succession of ecological diatom assemblages is observed at Hole 379A, from bottom to top:

1) Marine and relatively cold-water assemblage with *Coscinodiscus normanii* as its distinctive species. No such assemblage is known in the present-day population of the Black Sea. We find this assemblage in Sample 29-4 to 25-2, 45-47 cm.

2) Brackish-water and fresh-water halophile species assemblage characterized by *Stephanodiscus astraea*, a species common to the lakes of the Boreal region today. Although it can withstand a salinity as high as  $5 o/o_0$ , the assemblage is more frequent in purely fresh-water

Figure 1. Location of Leg 42B Sites 379, 380, 381.

lakes. It also contains *Stephanodiscus gravitoides* sp. nov. which does not occur elsewhere in the section. This assemblage is recorded in Samples 25-1, 8-9 cm to 17-1, 25-35 cm.

3) Marine warm-water assemblage entirely free of fresh-water diatoms and consisting of *Cyclotella caspia*, *Thalassiosira* aff. *oestrupii*, *Thalassiosira subsalina*, *Coscinodiscus perforatus*, and *Chaetoceros* spp. It was encountered between Samples 10, CC to 9-2, 10-12 cm. A similar assemblage of marine species is known in the Holocene sediments of the Black Sea (Shimkus et al., 1973).

4) Fresh-water halophile assemblage including brackish-water and sporadic marine diatoms. The relatively cold-water species *Stephanodiscus hantzschii* and *Cyclotella kutzingiana* are characteristic of this assemblage. *Stephanodiscus astraea* is also very abundant. The assemblage is characteristic of Samples 8, CC to 7, CC.

### Hole 380

The total number of examined samples is 65 from 27 cores. Samples 39, CC, 38, CC, 29, CC, 25, CC, 20, CC, 13, CC, 9, CC, 5-1, 82-84 cm, 2-5, 88-116 cm, 1-6, 50-52 cm, and 1-5, 50-78 cm were barren of diatoms. Sections 5-4, 7-1, 7-2, 7, CC, 32-5, and 32-6 were especially rich in diatoms.

At Site 380 the quantitative and qualitative variations of diatom composition proved to be identical to those at Hole 379A, despite the holes being widely separated.

### Hole 380A

The total number of examined samples from this hole is 94, obtained from 52 cores. Although 74 cores from Hole 380 were sampled, the interval from Sections 74-2 to 56, CC contained essentially no diatoms; sporadic benthic species were encountered. Nor were diatoms found within the interval from 31, CC to 18, CC. The highest numbers of diatom valves, well in excess of 200,000,000 to 400,000,000 valves/g, were recorded in Sections 50-2, 48-6, 45, CC, 45-3, 44, CC, 44-4, 43, CC, 42, CC, 42-2, 42-1, 41-6, 41-5, and 38-3. These are typical diatom-oozes. The second numerical gradation is below 200,000,000 valves/g, but more often it is about 100,000,000. The quantitative distribution is shown in Figure 4.

The qualitative diatom composition is varied. The following assemblages have been recognized from bottom to top:

1) Marine, relatively warm-water assemblage. *Hermisinum adriaticum* (family Ebriacea) and Archaeomonodacea are the most characteristic forms, the numbers of which increase toward the base of the marine unit. The marine flora is primarily characterized by *Actinocyclus ehrenbergii* and its different varieties. This is a sublittoral-neritic species typical of shoreline shallow-water biofacies and common to warm areas.

Figure 2. Distribution of diatoms, ebridians, and interpretation of the data, Hole 379A.

Besides Actinocyclus, the assemblage has the following characteristic species: Rhaphoneis maeotica, Rhizosolenia bezrukovii, Chaetoceros danicus, and

Figure 3. Distribution of diatoms, ebridians, and interpretation of the data, Hole 380.

Cyclotella proshkinae. This assemblage is characteristic of Samples 56, CC to 55-3, 55-57 cm.

The interval between Sections 54-1 and Core 50-2 has a mixed fresh-water marine diatom assemblage.

2) From Section 50-1 to Sample 32-1, 6-9 cm an assemblage of freshwater halophile diatom species prevails. From the diatom composition this thick interval can be regarded as lacustrine in origin.

The diatoms include *Melosira*, *Cyclotella*, and *Stephanodiscus*. The flora appears to be completely extinct except for one questionable species. *Melosira* includes a large number of archaic *Melosira* praegranulata and *M. bellicosa*. *M. praeislandica*, *M. hibschii*, *M. elegans*, and *M. papilio* (the latter two are new species) are markedly fewer in numbers. *Stephanodiscus* stands out as a special group within this fresh-water assemblage; its evolution is especially rapid and can be divided into four or five successive stages: (1) Stephanodiscus prohantzschii sp. nov.; (2) *S. kanitzii*; (3) *S. pontica* sp.nov.; (4) *S. dubius*; and (5) *Cyclotella* servant-vildary and its variety var. elegans, which crown the fresh-water close in structure to the members of the genus *Stephanodiscus*.

3) The third diatom assemblage occurs in Section 3-4 to Sample 1.1, 36-38 cm. The diatom composition of this upper part of Hole 380A is similar to that of the base of Holes 380 and 379A Sections 29-4 to 25-2, and can be correlated with the base of the two previous sections. The assemblage contains marine and freshwater halophile species represented by *Coscinodiscus normannii*, *Cyclotella caspia*, and *Stephanodiscus astraea*.

It is to be noted, however, that in Hole 380A, Samples 17-2, 111-123 cm to 7-1, 50-52 cm, we encountered a diatom assemblage which we had found neither at Hole 379A nor at Hole 380. Besides *Stephanodiscus astraea*, it also contains *Cyclotella corona* sp. nov. and, in our opinion, is a fresh-water assemblage.

### Site 381

The total number of 92 samples from 49 cores retrieved from Site 381 were examined. Samples 54-2, 15-16 cm to 39, CC and 20, CC to 4, CC were found barren of diatoms.

Coccoliths (old) and foraminifers are abundant in Section 40-1. Great amounts of pollen are present in Sample 38, CC, diluting the diatoms; similar layers are found in Sample 56, CC at Hole 380A. In the interval from Sample 38, CC to Core 21, CC typical diatom oozes have a high concentration of diatoms, and in this respect the interval is similar to Hole 380A, Samples 56-4, 77-79 cm to 38-3, 136-138 cm, and 32-1, 6-9 cm.

Qualitatively, the site is very much like Hole 380A. From bottom to top, the marine assemblage (38, CC to 34-6, 49-51 cm) is followed by an ecologically mixed assemblage, in which brackish-water and fresh-water species (34-3 to 33-4) occur along with marine ones. Further upward (32-1 to 20-1, 110-130 cm), most of the diatoms, of which halophiles prevail, are fresh-water.

The characteristic species of this lacustrine series are *Melosira*, *Cyclotella*, and *Stephanodiscus*. *Gyrosigma* aff. *acuminatum*, a very large form, sometimes 200  $\mu$ m long and morphologically different from the present-day form, is also common.

In Sample 3-3, 129-131 cm, Stephanodiscus astraea occurs in large numbers. In the uppermost layers (Samples 1-2, 20 cm, 1-3, 80 cm) the diatom composition can be regarded as marine, in which the northern boreal species Coscinodiscus normannii and the subtropical species Cyclotella caspia and

Figure 4. Distribution of diatoms, ebridians, and interpretation of the data, Hole 380A.

Figure 5. Distribution of diatoms, ebridians, and interpretation of the data, Site 381.

Figure 6. Distribution of diatoms and interpretation of the data, Core 1857.

Coscinodiscus perforatus are predominant, making it similar to Hole 380A, Samples 3-4, 46-61 cm to 1-6, 36-38 cm.

In our opinion, the available data on the youngest Black Sea sediments, dated as Holocene (Shimkus et al., 1973) should be added to the diatom characteristic of the examined sites. Large numbers of diatoms were found in the sediments of Core 1857 off the northwestern continental slope of the Black Sea.

In numbers and species composition, the sediments of the base of core 1857 correlate well with the sediments of the upper layers of Sites 379 and 380. The abundance in the sediments of these layers is low (no higher than 1,700,000 valves/g) and *Stephanodiscus astraea* is the most common species. These layers are of fresh water origin.

Marine sediments rich in diatoms (maximum high of 447,800,000 valves/g of sediment) are present higher in the section. Two stages can be distinguished in the marine sequence: (1) 114-50 cm with the neritic and neritic-pelagic species *Rhizosolenia setigera*, *Rhizosolenia calcar-avis*, *Rhizosolenia alata*, and

Cyclotella caspia. (2) 50-0 cm mostly with pelagic warm-water species such as *Chaetoceros peruvianus*, *Hemiaulus hauckii*, and *Thalassionema nitzschiodes*, which probably appeared as a result of free water exchange with the Mediterranean Sea.

Silicoflagellates, with the species *Distephanus* octonarius var. polyactis occurring in large numbers (up to 35,000,000 valves/g) is, besides diatoms, characteristic of the Holocene sediments of the Black Sea.

### BIOSTRATIGRAPHY AND PALEOGEOGRAPHICAL ENVIRONMENTS OF SEDIMENTATION

On the basis of diatom composition, the succession of Pliocene-Holocene sediments in the Black Sea can be readily subdivided into eight units representing alternating episodes of marine-brackish and freshwater subsaline conditions. Cool-water and warmwater periods in the history of sedimentation are less easily recognized. Diatoms enable us to define accurately the Pliocene-Pleistocene boundary at the top of a lacustrine sediment unit which contains fossil fresh-water diatoms belonging to *Melosira*, *Cyclotella*, and *Stephanodiscus* as characteristic species.

Unit 8, the oldest encountered unit of marine origin, occurs at the base of the diatom-bearing series at Hole 380A (Cores 56-55) and Site 381 (Sections 34-6 to 38-1). We treat Unit 8 as Pontian on the basis of similarities between the diatom assemblages and the pontic flora of the Taman Peninsula (Jousé, 1949).<sup>1</sup> The presence of older marine sediments remains problematic in that at Site 381 (Sections 37-2, 37-5 Sample 38-1, 127 cm) large numbers of *Raphoneis maeotica, Archaeomonos* spp. and *Hermisinum adriaticum* occur, suggesting a Meotian age.

Unit 7: Above marine Unit 8 is a sedimentary series of lacustrine origin characterized by fresh-water and fresh-water halophilic diatoms. It is more than 200 meters thick at Hole 380A (Cores 54-32) and 140 meters at Site 381 (Sections 34-3 to 20-1). The deposition of Unit 7 took place in late Pliocene when the Black Sea became isolated from the Mediterranean Sea and began changing into a lake-sea.

Throughout the depositional period of Unit 7 the diatom floral composition changed frequently, affecting mostly *Stephanodiscus* and *Cyclotella*; most of *Melosira* spp. remained unchanged. Diatoms of Unit 7 include many new species, descriptions of which are given in the Systematics section. Diatoms flourished during the whole of the lacustrine period probably because of rich biogenic elements that ascended into the euphotic zone from the depth. As a result, siliceous oozes characterize the sediments of Unit 7.

Lacustrine sediments of the Pliocene-Miocene, elsewhere in Europe are older than to those of the Black Sea. The lacustrine floras of Central Europe (Hungary,

<sup>&</sup>lt;sup>1</sup>In accordance with the latest stratigraphical scheme adopted at Bratislava in 1975, the Pontic stage corresponds to the close of the late Miocene (Messinian stage)—early Pliocene. It is not impossible that the layers containing Hermisinum adriaticum and cysts Archaeomonadaceae are already of the Meotis.

Austria, and Czechoslovakia) are much older, usually not younger than late Miocene (Reichert, 1899-1900; Hajos and Gyula, 1969); Hajos and Holzer, 1972; Rehakova, 1965, 1975). Rehakova (in a personal report) refers to the lacustrine biofacies of the late Miocene age in southern Czechia, which she calls the *Stephanodiscus* formation. The only locality similar in age to the Black Sea diatom floras is Lake Chad, the Pliocene sediment of which contain some Black-Sea species such as *Melosira praegranulata*, *Cyclotella servant-vildary* sp. nova, and *Stephanodiscus carconensis* (Servant-Vildary, 1973). There is also some similarity with the lacustrine Pliocene floras of France (Ehrlich, Ehrlich, 1967).

For all the possible analogies, however, the flora of the Black Sea as a whole is unusual and, indeed, endemic in some of its elements; the great number of new species is one evidence in this respect.

The evolution of diatoms was conspicuous during the Pliocene lacustrine stage of the Black Sea, and is particularly traceable in the evolution of *Stephanodiscus*, which numbers more than 10 species and several varieties. Because some *Stephanodiscus* species had a short time span, it is possible to subdivide the lacustrine series into four zones (from bottom to top): (1) *Stephanodiscus prohantzschii*, (2) *Stephanodiscus kanitzii*, (3) *Stephanodiscus pontica*, and (4) *Stephanodiscus dubius*. The series is crowned with layers containing *Cyclotella servant-vildary* and its variety *elegans*. In the summary stratigraphic tables (Figures 7 and 8) the stages are marked by the letters A, B, C, D.

The diversity of the taxonomic composition within certain intervals in Unit 7 is low; a single species may account for 80% to 90% of the total number of diatoms in some samples.

The upper part of lacustrine Unit 7 shows a gradual disappearance of the old species assemblage and it is on the basis of the last of its elements that we define the Pliocene-Pleistocene boundary.

Unit 6 succeeds the Pliocene-Pleistocene boundary. It is a thick terrigenous series at Holes 379A, 380, and Site 381, entirely barren of diatoms. The only exception is in the sediments of Hole 380A, Sample 17-2, 111-123 cm to 17-1, 50-52 cm, where an assemblage of diatoms with the hitherto unknown form *Cyclotella corona* sp. nov. as the most common species and with *Stephanodiscus astraea* and *Stephanodiscus hantzschii* in much less numbers occurs. Although Holes 379A and 380 were penetrated to 624.5 and 380 meters, respectively, they did not reach the lower boundary of sediments of Pleistocene age. On the basis of its stratigraphic position, Unit 6 is most likely of early Pleistocene age.

A complete change of the ecological environments at the close of the lacustrine period resulted in a prolonged retardation of evolution of the Black-Sea diatoms. Variation in the salinity of the basin, decrease in temperature due to the onset of the cold period, or a lack of nutritive salts in the surface waters were likely factors that contributed to, or were responsible for, the essential absence of diatoms in Unit 6.

Unit 5 is recognized at all Black Sea holes drilled by *Glomar Challenger*. At Hole 379A, it occurs in Samples 30-2, 30-32 cm to 25-2, 45-47 cm, at Hole 380, in

Figure 7. Correlation of the diatom units of the Black Sea.

Samples 39-6, 50-52 cm to 35-1, 111-123 cm, at Hole 380A, in Samples 3-4, 46-61 cm, to 1-1, 36-38 cm and at Site 381, in Samples 4, CC to 1-2, 20-40 cm; Unit 5 is at the top of the drilled sediments of the latter two sites.

Most of the diatoms within Unit 5 are marine species, but fresh-water and brackish-water species are also in considerable numbers. *Coscinodiscus normannii*, a boreal, relatively cool-water marine species is very abundant, and can be taken as the index species.

According to the stratigraphic scheme of the Quaternary Period of the Black Sea basin proposed by Arkhangelskiy and Strakhov (1938), Unit 5 correlates well with the Drevne-euxinian (Fedorov, 1963).

Unit 4 is a thick unit occuring at Hole 379A in Samples 25-1 to 11, CC, and at Hole 380, in Samples 33, CC to 12-1, 140-141 cm.

The diatom distribution makes it possible to distinguish within Unit 4, at Hole 379A, the following stratigraphic intervals. At the base, from 25-1, 8-9 cm to 24-4, 133-135 cm, there is a maximum of 167,000,000 valves/g; in the second layer, 24-4, 133-135 cm, to 19-1

Figure 8. Correlation of the diatom data at Black Sea and Alpian stratigraphic scale.

the overall number of diatoms does not exceed 3,000,000 valves/g; in the third layer, 18, CC to 17-1, 25-35 cm, there are approximately 10,000,000 valves/g; and in the fourth layer, 16, CC to 11, CC diatom valves are rare and occur sporadically in individual samples.

A similar abundance curve is found for Site 380.

The diatom flora of Unit 4 is mostly fresh water with some brackish-water and marine species. Consequently, it is postulated that a fresh-water basin existed during the depositional period of Unit 4, and climatic conditions changed repeatedly with warm stages charcterized by a high diatom productivity (layers I and III) alternating with cooler stages during which the productivity was low (layers II and IV).

According to the stratigraphic scheme of the Quaternary period of the Black Sea basin, Unit 4 combines Paleouzunfar and Uzunlar sediments.

Unit 3 is readily identified by a definite Pleistocene marine diatom flora. The marine flora is especially characteristic of, and abundant in, the lower part of the unit (Hole 379A, Samples 10, CC to 9-3, 94-96 cm), but toward the upper boundary the marine assemblage diminishes and fresh-water and brackish-water diatoms become abundant. This fresh-water assemblage is common to Hole 379A, Samples 9-2, 10-12 cm to 7, CC, and to Hole 380.

The marine assemblage is characterized by the presence of such warm-water species as *Thalassiosira* aff. oestrupii, *Thalassiosira subsalina*, *Coscinodiscus perforatus*, *Cyclotella caspia*, *Chaetoceros* spp. (spores). *Thalassiosira oestrupii* has not been recognized in the present-day population of the Black Sea (Proshkina-Lavrenko, 1955), although it existed in the Holocene (Shimkus et al., 1973).

In diatom characteristics, Unit 3 correlates well with the paleogeographical environments of the Karangat interglacial epoch (Eemian in Western Europe or Mikulino in the territory of the USSR) (Markov et al., 1965; Arslanov et al., 1976).

Unit 2 combines the series of sediments of Hole

379A, Samples 6, CC to 1-4, 28-30 cm and Hole 380, Samples 5-3, 49-62 cm to 0, CC with the base of Core 1957 in the interval of 265 to 114 cm.

Unit 2 is deficient in diatom remains; none in fact were found in some of the samples. Of the species encountered, the fresh-water *Stephanodiscus astraea* was most frequent.

On the basis of species composition and quantitative distribution of the diatoms of Unit 2, we are able to relate the unit to the last glacial epoch (Würm, Valdaj). Following the stratigraphic scheme of the Pleistocene of the Black Sea, Unit 2 corresponds to the Novoeuxinian epoch.

The paleogeographical conditions of deposition of Unit 2 are similar to those of Unit 6.

Unit 1 is identified on the basis of diatom evidence in Core 1857, as being Holocene. The diatoms are marine and the species composition is close to the present-day Black Sea flora.

#### CONCLUSIONS

1. In this first opportunity to study the late Tertiary diatom assemblages of the Black Sea, it has become apparent that, during the Pleistocene a regular alternation of fresh-water species assemblages deposited during the cold epochs, with brackish-water marine and marine species deposited during the warm epochs occurred. The warmest and most dominant marine assemblage of diatoms corresponds to the Karangat (Riss-Würm). In the intervals correlating with the cold epochs the diversity and abundance of diatoms fall sharply.

The Pliocene-Pleistocene boundary is readily recognizable by the extinction of old (on the whole fossil) fresh-water diatoms.

2. In the late Pliocene the Black Sea was a vast lake in which sediments of the diatom ooze type accumulated. The vertical distribution of diatoms during the late Pliocene shows four stages of evolution. The earliest is characterized by a fresh-water and brackish-water diatom flora and is regarded as a transitional stage. The next three stages represent lacustrine environments; diatoms within them include members of the three genera *Melosira*, *Cyclotella*, and *Stephanodiscus* which are common representatives of a lacustrine flora.

3. Below the lacustrine diatom series of the late Pliocene sediments are clayish marine sediments. They are characterized by a planktonic diatom flora with Actinocyclus, Rhaphoneis, Chaetoceros, Rhizosolenia, Actinoptychus, and Cyclotella as type genera, and diverse benthic marine species. Besides diatoms, the marine series at the base of Hole 380A and Site 381 is characterized by large numbers of Hermisinum adriaticum, a member of the family Ebriacea, and spores of the Archaeomonodacea type. Proceeding from the great similarity between the diatom composition in the sea sediments examined and that of the known show pontic sediments (the Taman Peninsula), we correlate this marine series containing Actinocyclus ehrenbergii to the Pontian Maeotian stage.

The Stratigraphical scheme we are proposing for the Pliocene-Pleistocene sediments of the Black Sea is to be regarded as tentative and demands further elaboration, since we have no data on the absolute age of the sediments and on the paleomagnetic stratigraphy.

#### SYSTEMATICS

#### Coscinodiscus normannii Greg.

(Plate 16, Figures 1-10; Plate 18, Figures 1-6, 10-12)

Description: Jousé, Diatomic Analysis (1949), p. 63, pl. 19, fig. 4a-b.

DSDP Leg 42B occurrences: Found in varying abundance in the Pleistocene sections of Holes 379A and 380.

Coscinodiscus aff. stokesianus (Grev.) Grunow (Plate 4, Figures 7-9)

Description: Rehakova (1965), p. 30, pl. IX, fig. 3-7.

DSDP Leg 42B occurrences: Found abundant to common in the early Pliocene sections of Holes 380A (Cores 51-54) and 381 (Cores 33-34).

#### Cyclotella caspia Grunow

(Plate 19, Figures 6-9; Plate 20, Figures 9, 10; Plate 22, Figure 8)

Description: Proshkina-Lavrenko (1955), p. 61, pl. II, fig. 1-8. DSDP Leg 42B occurrences: Found in varying abundance in the Pleistocene sections of Holes 379A, 380, and in the Holocene sections of Core 1857.

#### Cyclotella corona Mukhina sp. nov. (Plate 15, Figures 2-10)

**Description:** Valve thick-walled, convex, 25-35  $\mu$ m in diameter. The marginal zone is about two-thirds of the radius in width, with radial striae becoming furcate at the edge. The marginal zone is often fracturable. The central area is large, clearly bounded and raised over the marginal zone, at times irregular. A ring of large punctae near the edge of the central area; at times two or three punctae at the center of the area.

DSDP Leg 42B occurrences: Fresh-water species, early Pleistocene. Hole 380A, Sample 17-1, 50-52 cm—abundant; Sample 17-1, 87-89 cm; 17-2, 111-123 cm—common.

Holotype: Plate 15, Figure 5; from Leg 42B, Sample 380A, 17-2, 111-123 cm, Black Sea.

Paratype: Plate 15, Figures 2-4, 6-10.

#### Cyclotella proshkinae Jousé et Mukhina sp. nov. (Plate 3, Figures 5-11; Plate 4, Figure 12)

**Description**: Valves small,  $5-10 \,\mu$ m in diameter. A transverse plication is sometimes visible. The middle part of the valve is thickly granular. The margin narrow (often fractured), finely striated, and visible at magnification 2000-3000 in SEM.

**Remarks**; zespecies istnametin.honor of A. I. Proshkina-Lavrenko; a well-known scientist of the Black Sea diatoms.

DSDP Leg 42B occurrences: Brackish-water species; early Pliocene. Hole 380A, Cores 33-34, common.

Holotype: Plate 4, Figure 12; from Leg 42B, Sample 380A-54-1, 66-78 cm, Black Sea.

#### Cyclotella kutzingiana Thwaites

(Plate 19, Figure 12; Plate 20, Figures 1-8)

Description: Hustedt (1930), p. 338, pl. 1, fig. 171.

DSDP Leg 42B occurrences: Found in varying abundance in the Pleistocene sections of Holes 379A and 380.

#### Cyclotella praekutzingiana Mukhina sp. nov. (Plate 3, Figures 5-11)

**Description:** Valves flat or slightly convex, at times with a tangential plication, from 5 to 18  $\mu$ m in diameter. The marginal zone often wide, from one-third to one-half of the valve diameter. The surface of the marginal zone is finely striated; striae vary in length. The middle part of the valve is finely granular. A smooth hyaline zone is often present between the striated peripheral zone and the granular middle zone. The margin has one process. This species is similar to *Cyclotella kutzingiana* from Lake Hula of Northern Israel (Ehrlich, 1973).

DSDP Leg 42B occurrences: Brackish-water marine species. Éarly Pliocene (Pontian stage). Hole 380A, Core 55, few; Hole 381, Cores 35, 38, abundant.

Holotype: Plate 3, Figure 5; from Leg 42B, Sample 381-35-5, 105-120 cm, Black Sea.

Paratype: Plate 3, Figures 6-11.

#### Cyclotella servant-vildary Mukhina sp. nov.

(Plate 8, Figure 1; Plate 10, Figures 5-15; Plate 11, Figures 1-2, 4-11; Plate 14, Figures 3-4, 7-8)

Description: Valves flat, 5-30 µm in diameter. The margin is well pronounced, very narrow (2-3 µm), finely striated, often fracturable. Rare radial rows of large areolae occur on the surface of the valve. The number of the rows depends on the valve diameter (varying from 6 to 15 around the circumference). No spines are present.

Remarks: The species shows a high degree of polymorphism. It is identical with Cyclotella sp. (Servant-Vildary, 1973, pl. 10, fig. 1-3) from the sediments of Lake Chad.

DSDP Leg 42B occurrences: Fresh-water species; late Pliocene. Hole 380A, Cores 32-40, abundant. Hole 381, Cores 22-26, common.

Holotype: Plate 11, Figure 9: from Leg 42B, Sample 380A, 35-3, (58-71 cm), Black Sea.

Paratype: Plate 8, Figure 1; Plate 10, Figures 5-15. Plate 11, Figures 1-2, 4-8, 10-11; Plate 14, Figures 3-4, 7-8.

#### C. servant-vildary var. elegans var. nov.

(Plate 8, Figure 2; Plate 10, Figures 1-4; Plate 11, Figure 12; Plate 14, Figures 1-2)

Remarks: Differs from the type in that margin is broader and the rows of areqlae have a fine, more dense structure; 15 µm to 20 µm in diameter on the average.

DSDP Leg 42B occurrences: Found together with the species; the vertical range is short. Hole 380A, Sample 32-1, 6-9 cm, abundant.

Holotype: Plate 10, Figure 1; from Leg 42B, Sample 380A-32-1, 6-9 cm, Black Sea.

Paratype: Plate 8, Figure 2; Plate 10, Figures 2-4; Plate 11, Figure 12; Plate 14, Figures 1-2.

#### Gyrosigma aff. acuminatum (Ktz.) Rbh.

Description: Jousé, Diatomic Analysis (19549), 248, pl. 80, fig. 9. Remarks: Valve linear, narrowing slightly toward the apices. 200-400  $\mu$ m long and about 20 $\mu$ m wide. The axial area and raphe are thread-like. The central area is very small and the central nodule hardly visible. The striae transverse, linear, 20-22 in 10 µm. Commonly there are longitudinal striae, but often they are absent.

DSDP Leg 42B occurrences: Fresh-water-subsaline-water species. Hole 380A, Cores 38-41, rare. Hole 381, Cores 29-31, common. No illustration.

#### Melosira bellicosa Heribaud

(Plate 6, Figure 15; Plate 12, Figures 10, 12-15)

Description: Heribaud (1903), p. 93, pl. 12, fig. 23.

Remarks: Valves cylindrical, diameter and height approximately equal; 8-10  $\mu$ m in diameter, 7-10  $\mu$ m in height. At the base of the valve there is a deep sulcus which separates a hyaline broad collar. Longitudinal ridges cross the valve surface, with rare elongate areolae scattered between the ridges. Spines are arranged around the valve disk

Resting spores of this species are also found in the sediments. They have dome-shaped valves and a very broad band. The valves differ in structure; the structure of one is more rarified and finer than that of the other.

Typical M. bellicosa is known from the late Pliocene of France (Heribaud, 1903), Ehrlich (1967) in Villafranch.

DSDP Leg 42B occurrences: Fresh-water species. Found together with Melosira praegranulata and Melosira hibschii. Occurs in varying abundance in the late Pliocene section of Holes 380A and 381.

#### Melosira elegans Mukhina sp. nov. (Plate 9, Figures 5-7)

Description: Frustule cylindrical, thin-walled, 30-35 µm high. Valves 10-13 µm in diameter, often widened at the ends. The free end of the valve has a narrow hyaline collar. The sulcus is hardly visible, the joint of the valves is very tight, with minute denticles between the valves. Valve areolate. Areolae flat, tightly adjoining one another, light colored, arranged in regular rows, 12 rows of areolae in 10 µm.

DSDP Leg 42B occurrences: Always found together with Melosira praegranulata and Melosira bellicosa, but in less numbers. Freshwater species; late Pliocene. Holes 380A, 381, abundant.

Holotype: Plate 9, Figure 5; from Leg 42B, Sample 380A-39-3, 99-101 cm, Black Sea.

Paratype: Plate 9, Figures 6. 7.

#### Melosira hibschii Reichert

(Plate 6, Figure 16; Plate 12, Figures 2, 3, 6, 7)

Description: Rehakova (1969), pl. 2, Fig. 34-37.

Remarks: Frustules and valves of vegetative cells, as well as resting spores having a barrel-shaped form and dome-shaped valves. Vegetative cells have flat valves. Dome-shaped valves and flat valves are equal in size; 18-20 µm in diameter and 15 µm high. Shallow sulcus separates a hyaline band. Valve disk thickly areolate, areolae varying in size. Over the edge of the disk there is a ring of elongate large areolae similar in form to the areolae at the valve fold.

DSDP Leg 42B occurrences: Fresh-water species. Encountered together with Melosira praegranulata. Found in varying abundance in the late Pliocene sections of Holes 380A and 381.

# Melosira papilio Mukhina sp. nov. (Plate 5, Figures 1, 2, 11-14)

Description: Valves small, bell-shaped, 5-6 µm high. Jointed with a broad girdle with numerous intercalary bands. The structure is finely porous. Often the valves are covered with minute spines. One process is near the sulcus. Valves form short curved chains.

DSDP Leg 42B occurrences: Brackish-water fresh-water species. Characteristic of the early stage of the late Pliocene. Holes 380A, Cores 43-47; 381, Cores 29-35.1, common.

Holotype: Plate 5, Figure 1; from Leg 42B, Sample 381, 32-1, 31-34 cm. Black Sea.

Paratype: Plate 5, Figures 2, 11-14.

#### Melosira praegranulata Jousé

(Plate 5, Figures 3-9; Plate 9, Figures 8, 9; Plate 12, Figures 8, 9, 11)

Description: Jousé (1952), p. 24l, pl. 3, fig. 8, 9.

Remarks: The species shows a high degree of polymorphism. Servant-Vildary (1973) refers to the presence of ocelles on the valve of M. praegranulata, which, when viewed in optical microscope, look like a ring 2  $\mu$ m in diamter near the sulcus on the outside surface of the valve, which seems to open into the interior of the valve. This element of the structure has not been found in our material.

DSDP Leg 42B occurrences: Fresh-water, probably halophile species. One of the most characteristic and massive in the Melosira assemblage during the late Pliocene Holes 380A, Cores 36, CC to 54-1; 381, Cores 20 to 34-3.

#### M. praegranulata f. curvata Jousé (Plate 9, Figures 10-16)

Description: Jousé (1952), p. 241, pl. 3, fig. 9.

DSDP Leg 42B occurrences: Found together with the species. The vertical range is restricted. Sites 380A, Cores 36-39; 381, Cores 20-22, Section 3, common.

#### Melosira praeislandica Jousé (Plate 5, Figure 10)

Description: Jousé (1952), p. 241, pl. 3, fig. 1-2, 5. DSDP Leg 42B occurrences: Fresh-water halophile species. Common in the late Pliocene section of Holes 380A and 381. Diatoms of the USSR, v. 1, pl. 44, fig. 3

#### Rhaphoneis maestica (Milovanova) Sheshuk and Gleser (Plate 2, Figures 8-14)

Description: Valves linear, straight and curved, at times slightly widened at the ends and in the middle, 20-70 µm long and 2-4 µm wide. The axial area is thread-like. The pores form regular transverse rows, 16 rows in 10  $\mu$ m. Some forms have a thick meshwork of minute pores at the poles of the valves. Form chain colonies.

DSDP Leg 42B occurrences: Marine species; early Pliocene (Pontian-Maeotian stage). Hole 380A, Core 56; 381, Cores 35, 38, abundant.

Holotype: Plate 2, Figure 9; from Leg 42B, Sample 381-35-5, 105-120 cm, Black Sea.

Paratype: Plate 2, Figures 8, 10-14.

#### Rhizosolenia bezrukovii Jousé sp. nov.

(Plate 1, Figures 12-13)

**Description:** Frustule cylindrical, from 6 to 22  $\mu$ m in diameter. Valve funnel-shaped turning into a very long, thin process 100-200  $\mu$ m in length. The process is either straight or curved, slightly tapering toward the free end. The surface of the process is finely granular. Two transparent setulae protrude from the valve disk. The valve surface is smooth. The numerous intercalary bands of the frustule are collar-shaped.

**Remarks:** The species is named in honor of Professor P.L. Bezrukova, marine geologist and sedimentologist.

DSDP Leg 42B occurrences: Marine species; early Pliocene (Pontian Stage). Holes 380A, Core 56.3; 381, Core 35.5, abundant.

Holotype: Plate 1, Figure 12; from Leg 42B, Sample 381, 35-5, 57-59 cm, Black Sea.

Paratype: Plate 1, Figure 13.

#### Stephanodiscus astraea (Ehr.) Grunow

(Plate 15, Figure 1; Plate 17, Figures 4-10; Plate 20, Figures 12-13; Plate 21, Figures 1-3; Plate 22, Figure 2)

Description: Hustedt (1930), p. 368-369, fig. 193.

DSDP Leg 42B occurrences: Found in varying abundance in the Pleistocene sections of Sites 379A, 380 and in some samples in the Holocene section of Core 1857.

#### Stephanodiscus carconensis Grunow

(Plate 2, Figures 1-4; Plate 3, Figures 12-13; Plate 4, Figures 1-4; Plate 13, Figures 10-12)

Description: Servant-Vildary (1973), pl 367-368, fig. 192.

DSDP Leg 42 occurrences: Found abundant in the late Pliocene sections of Holes 380A and 381.

#### Stephanodiscus gravitoides Mukhina sp. nov. (Plate 17, Figures 11-12)

**Description:** Valve greatly convex, 22.5-37  $\mu$ m in diameter. Areolae arranged in radial rows, 10 areolae in 10  $\mu$ m near the center and 12 areolae in 10  $\mu$ m at the edge. The center is at times lacking structure. Single rows of areolae near the edge turn into double rows. The margin area narrow, porous, with rare spikes, 2 spikes in 10  $\mu$ m.

DSDP Leg 42B occurrences: Fresh-water halophil species. Quaternary. Hole 379A, Cores 24-25; 380, Cores 17-18, 22, 32-33, common.

Holotype: Plate 17, Figure 11; from Leg 42B, Sample 379A-24-6, 21-23 cm, Black Sea.

Paratype: Plate 17, Figure 12.

#### Stephanodiscus hantzschii Grunow

(Plate 15, Figure 11; Plate 21, Figures 7, 8)

Description: Hustedt (1930), p. 370, fig. 194.

DSDP Leg 42B occurrences: Found common in the Pleistocene and late Pliocene sections of Holes 380A and 381.

#### Stephanodiscus marginatus Mukhina sp. nov. (Plate 6, Figure 9; Plate 9, Figure 3)

**Description**: Valve uniformly convex, 15-47  $\mu$ m in diameter. It has a broad margin distinctly separated from the valve. The margin surface is covered with ribs, 7 ribs in 10  $\mu$ m. The margin zone has coarse rare spikes.

Between ribs there are fascicles of small pores which continue for a short distance over the peripheral zone of the valve. The middle part of the valve is thickly covered with areolae in random arrangement, varying in size. Isolated pores occur among the areolae.

DSDP Leg 42B occurrences: Fresh-water species; late Pliocene. Hole 380A, Core 38-49: 381, Cores 22-29, common.

Holotype: Plate 6, Figure 9; from Leg 42B, Sample 381-28-2, 78-80 cm, Black Sea.

Paratype: Plate 9, Figure 3.

#### Stephanodiscus pontica Jousé sp. nov.

(Plate 6, Figures 11-13; Plate 7, Figures 1-12; Plate 8, Figures 4-12)

**Description**: Valves broadly triangular, rounded, at times crescent, the dorsal side convex, the ventral side concave. The center of the valve is always offset toward the dorsal side. Rounded valves  $5-20 \,\mu\text{m}$  in diameter, the long axis of triangular forms  $5-20 \,\mu\text{m}$  long,  $10-15 \,\mu\text{m}$  high.

The rows of areolae are arranged in fan-shaped divergent fascicles; 2 to 3 rows of areolae in each fascicle near the edge of one row toward the center. There are minute spikes at the base of each fascicle.

**Remarks**: The species has a high degree of polymorphism. Some rounded forms are very akin to *Stephanodiscus kanitzii*.

DSDP Leg 42B occurrences: Brackish-water species (up to 5°/00); late Pliocene. Holes 380A, Cores 41-45; 381, Cores 26-28, abundant.

Holotype: Plate 7, Figure 7; from Leg 42B, Sample 381-27-2, 50-68 cm, Black Sea.

Paratype: Plate 6, Figures 11-13; Plate 7, Figures 1-6, 8-12; Plate 8, Figures 4-12.

#### Stephanodiscus prohantzschii Jousé sp. nov. (Plate 4, Figures 10-11)

**Description:** Valve flat, 10-32  $\mu$ m in diameter. Valve fold 5  $\mu$ m wide. Small pores arranged in more or less regular rows, 15-16 rows in 10  $\mu$ m, the fascicles indistinct, narrow (2 rows of pores each). The pores are somewhat rarified at the center. One pore is larger and convex, of the nodule type. The margin has dense spikes interwoven to form a peculiar fringe, 8 spikes in 10  $\mu$ m.

The valve fold is finely striated, at times with minute costae in descussate order. Colonies are common, in which cells are tightly connected with one another.

**Remarks:** The species seems to form on evolutionary series with *Stephanodiscus hantzschii*. There is a definite similarity in valve structure between the two species.

DSDP Leg 42B occurrences: Brackish-water species; late Pliocene. Sites 380A, Cores 46-54; 381, Cores 28-34, common.

Holotype: Plate 4, Figure 10.

#### Thalassiosira makarovae Mukhina sp. nov. (Plate 6, Figure 14)

**Description:** Valve flat, 45-60  $\mu$ m in diameter. The structure is finely aerolate, 14-16 areolae in 10  $\mu$ m. The areolae are arranged in linear and tangential rows. Small spikes (processes) are scattered all over the valve. One row of spines, 8 to 9 in 10  $\mu$ m, at the margin. The valve is yellowish.

Remarks: The species is named in honor of I. V. Makarova, an algologist.

DSDP Leg 42B occurrences: Salt-water fresh-water species; late Pliocene. Hole 380A, Cores 43, 46; 381, Cores 29-30, rare.

Holotype: Plate 6, Figure 14, from Leg 42B, Sample 380A-43-2m 79-87 cm.

#### Thalassiosira aff. oestrupii (Ostf.) Proshkina-Lavrenko (Plate 19, Figures 1-5; Plate 22, Figures 3-6)

Description: Hasle (1960), p. 8, pl. 1, fig. 5-7.

DSDP Leg 42B occurrences: Found in varying abundance in the Pleistocene sections of Holes 379A, 380, and in the Holocene sections of Core 1857.

Thalassiosira subsalina Proshkina-Lavrenko (Plate 18, Figure 9; Plate 21, Figures 9-12)

Description: Proshkina-Lavrenko (1955), p. 64, pl. 11, fig. 4. DSDP Leg 42B occurrences: Found in varying abundance in the Pleistocene sections of Holes 379A and 380.

#### ACKNOWLEDGMENTS

The authors are very grateful to Professors Dr. D. Ross and Dr. Y. Neprochnov for an opportunity to study Diatoms in the cores from the Black Sea (Leg 42B). The authors thank Professors P.L. Bezrukov and A.P. Lisitsin who have read our manuscript and made valuable critical remarks. We are also very grateful for the help of our colleague N. Spasskaya who prepared most of the samples and slides. Thanks are also due to Mrs. A.Y. Shevchenko for her help with SEM (scanning electron microscope).
