

## APPENDIX: INTERLABORATORY COMPARISON OF LEG 69 AND 70 BASALT STANDARDS<sup>1</sup>

Hans-W. Hubberten,<sup>2</sup> Institut für Petrographie und Geochemie der Universität Karlsruhe, Karlsruhe, Federal Republic of Germany  
and

Joan H. Splain, Rosenstiel School of Marine and Atmospheric Science, University of Miami, Miami, Florida

To provide an interlaboratory comparison, the laboratories that participated in the analysis of the Leg 69 and 70 basalts were asked to analyze three samples taken from Holes 510 and 504B. Sample IC I was Sample 501-10-1 (69–83 cm), pieces 115 and 116. Sample IC II was Sample 504B-36-1 (91–110 cm), piece 301. Sample IC III was Sample 504B-40-2 (72–88 cm), piece 532. All the samples were fine-grained, homogeneous, and relatively fresh in hand specimen. Sample weights exceeded 150 g.

The samples were taken to Karlsruhe, cleaned with distilled water, crushed with help of a hydraulic press, and powdered using an agate mill. The samples were then homogenized and split by using a sample divider. After the samples were divided into eight portions, portions 1, 3, 5, 7 and 2, 4, 6, 8 were put together again, forming divisions labeled A and B. These divisions were divided again into eight portions each, for a total of 16 portions for each sample. One or more of these portions were sent to 12 laboratories, 9 of which returned results. The results for the major elements are presented in Tables 1 to 3. The nine laboratories (and, where given, publications that give the results of hard-rock analyses made therein) are the Woods Hole Oceanographic Institution (WHOI), the Vernadsky Institute of Geochemistry and Analytical Chemistry, Moscow (VIG, Sharashkin et al., this volume), the Department of Geology and Geography, University of Alabama (ALA), the Centre Océanologique de Bretagne, Brest, France (COB, Etoubleau et al., this volume), the Institut für Petrographie und Geochemie der Universität Karlsruhe, Karlsruhe, Federal Republic of Germany (UKAR, Hubberten et al., this volume), the Department of Geology, University of Newcastle upon Tyne, United Kingdom (UNUT), the Institute of Geology of Ore Deposits, Petrography Mineralogy, and Geochemistry, Moscow (IGOD, Perssev and Boronikhin, this volume), the Institut Dolomieu, Université de Grenoble, France (UGRE, Laverne and Vivier, in press), and the Centre de Séimentologie et Géochimie de la Surface, Strasbourg, France (CSGS, Honnorez et al., in press).<sup>3</sup>

<sup>1</sup> Cann, J. R., Langseth, M. G., Honnorez, J., Von Herzen, R. P., White, S. M., et al., *Init. Repts. DSDP*, 69: Washington (U.S. Govt. Printing Office).

<sup>2</sup> Present address: Inst. de Geología, Universidad Autónoma de Nuevo León, 67700 Linares, N.L., Mexico.

<sup>3</sup> Analysts and methods used, as given by analysts, are as follows: WHOI—G. Thompson, XRF, ignition; VIG—A. A. Migdisov, chemical, INAA, AAS (preliminary results only); ALA—S. H. Stow, AAS; COB—O. Corre and H. Bougault, XRF, ignition; UKAR—M. Grünhäuser and U. Kramar, XRF, INAA; UNUT—P. J. Oakley; IGOD—G. S. Esikova and S. I. Vronskaya, XRF, AAS; UGRE—G. Vivier, XRF; CSGS—Y. Besnus, spectromètre d'arc.

To permit the analyses to be compared, each analysis was recalculated to a dry and reduced state and then normalized to 100 percent. In Tables 4 to 6 these values are presented along with their means and standard deviations (SD). The results of the Vernadsky Institute of Geochemistry (VIG) were not used in calculating the mean and SD because they were sent as preliminary data only.

To present one example of the variations among different laboratories in a different way, the FeO\* and MgO values obtained on the three standard samples are plotted in Figure 1 as well as the calculated mean.

The homogeneity of the samples can be tested by comparing the analyses for the portions in Divisions A and B of Sample IC I. As can be seen from Table 4, the agreement between IC I A and IC I B is good, with variations that lie within the SD for either. In further discussions the portions in Divisions A and B are therefore considered identical within the uncertainty of analysis.

The results from the different laboratories are in fairly good agreement. However, the standard deviations are larger than in earlier DSDP interlaboratory comparisons (Wright, 1977; Kirkpatrick et al., 1979; Natland et al., 1979 and Staudigel, 1980). There are also systematic deviations from the mean for some of the oxides analyzed by the laboratories (Table 7). The deviations from the mean do not represent deviations from "correct" values, since the calculated mean is based on only 8 analyses. However, they make it clear that care must be taken when data from one laboratory are compared with data from another. Furthermore, they indicate that these data, which were produced as routine analyses, must be considered to have a larger uncertainty than previous data on standard shipboard samples. Differences between different laboratories of 1.5% in SiO<sub>2</sub>, 1% in Al<sub>2</sub>O<sub>3</sub>, 1% in FeO\*, 0.6% in CaO, 0.5% in MgO and 0.5% in Na<sub>2</sub>O are larger than satisfactory, in our opinion, even for routine analyses.

The trace element data (Tables 8 to 10) show about the same percentages of variation as the major element data (the VIG data are preliminary).

In conclusion, there are systematic differences between the laboratories involved in the investigation of the Costa Rica Rift basalts. The differences are too large to allow comparison of the data from different laboratories for such purposes as detailed discussions of chemical stratigraphy. However, the variations are not large enough to affect the normative classification of the rocks or general elemental variations resulting from such processes as crystal fractionation.
